Strings in C

Saif Nalband PhD

Learning Goals

- Learn how strings are represented in C; as an array of null-terminated characters.
- Understand how to use the built-in string functions for common string tasks
- Learn about buffer overflow and what might cause it

Lecture Plan

- Characters
- Strings
- Common String Operations
 - Comparing
 - Copying
 - Concatenating
 - Substrings

Lecture Plan

 - Concatenating
 - Substrings

Char

A **char** is a variable type that represents a single character or "glyph".

```
char letterA = 'A';
char plus = '+';
char zero = '0';
char space = ' ';
char newLine = '\n';
char tab = '\t';
char singleQuote = '\'';
char backSlash = '\\';
```

ASCII

Under the hood, C represents each **char** as an *integer* (its "ASCII value").

- Uppercase letters are sequentially numbered
- Lowercase letters are sequentially numbered
- Digits are sequentially numbered
- Lowercase letters are 32 more than their uppercase equivalents (bit flip!)

ASCII

We can take advantage of C representing each **char** as an *integer*:

```
// true
bool areEqual = 'A' == 'A';
bool earlierLetter = 'f' < 'c';  // false</pre>
char uppercaseB = 'A' + 1;
int diff = 'c' - 'a';
                                  // 2
int numLettersInAlphabet = 'z' - 'a' + 1;
// or
int numLettersInAlphabet = 'Z' - 'A' + 1;
```

ASCII

We can take advantage of C representing each **char** as an *integer*:

```
// prints out every lowercase character
for (char ch = 'a'; ch <= 'z'; ch++) {
    printf("%c", ch);
}</pre>
```

Common ctype.h Functions

Function	Description
isalpha(<i>ch</i>)	true if <i>ch</i> is 'a' through 'z' or 'A' through 'Z'
islower(<i>ch</i>)	true if <i>ch</i> is 'a' through 'z'
isupper(<i>ch</i>)	true if <i>ch</i> is 'A' through 'Z'
isspace(<i>ch</i>)	true if <i>ch</i> is a space, tab, new line, etc.
isdigit(<i>ch</i>)	true if <i>ch</i> is '0' through '9'
toupper(<i>ch</i>)	returns uppercase equivalent of a letter
tolower(<i>ch</i>)	returns lowercase equivalent of a letter

Remember: these **return** a char; they cannot modify an existing char!

More documentation with man isalpha, man tolower

C Strings

C has no dedicated variable type for strings. Instead, a string is represented as an **array of characters** with a special ending sentinel value.

'\0' is the **null-terminating character**; you always need to allocate one extra space in an array for it.

C Strings

```
char myString[6];
myString[0] = 'H';
myString[1] = 'e';
myString[2] = 'l';
...
myString[5] = '\0';
```

String Length

Strings are <u>not</u> objects. They do not embed additional information (e.g., string length). We must calculate this!

index	0	1	2	3	4	5	6	7	8	9	10	11	12	13
value	'H'	'e'	'1'	'1'	'0'	' '		'w'	'o'	'r'	'1'	'd'	'!'	'\0'

We can use the provided **strlen** function to calculate string length. The null-terminating character does *not* count towards the length.

```
int length = strlen(myStr);  // e.g. 13
```

Caution: strlen is O(N) because it must scan the entire string! We should save the value if we plan to refer to the length later.

C Strings As Parameters

```
When we pass a string as a parameter, it is passed as a char *. C passes the
location of the first character rather than a copy of the whole array.
int doSomething(char *str) {
char myString[6];
doSomething(myString);
```

C Strings As Parameters

```
When we pass a string as a parameter, it is passed as a char *. C passes the
location of the first character rather than a copy of the whole array.
int doSomething(char *str) {
     str[0] = 'c'; // modifies original string!
     printf("%s\n", str); // prints cello
                                         We can still use a char * the
                                         same way as a char[].
char myString[6];
... // e.g. this string is "Hello"
doSomething(myString);
```

Common string.h Functions

Function	Description
strlen(<i>str</i>)	returns the # of chars in a C string (before null-terminating character).
<pre>strcmp(str1, str2), strncmp(str1, str2, n)</pre>	compares two strings; returns 0 if identical, <0 if str1 comes before str2 in alphabet, >0 if str1 comes after str2 in alphabet. strncmp stops comparing after at most n characters.
strchr(<i>str, ch</i>) strrchr(<i>str, ch</i>)	character search: returns a pointer to the first occurrence of <i>ch</i> in <i>str</i> , or <i>NULL</i> if <i>ch</i> was not found in <i>str</i> . strrchr find the last occurrence.
strstr(<i>haystack</i> , <i>needle</i>)	string search: returns a pointer to the start of the first occurrence of needle in haystack, or NULL if needle was not found in haystack.
<pre>strcpy(dst, src), strncpy(dst, src, n)</pre>	copies characters in src to dst , including null-terminating character. Assumes enough space in dst . Strings must not overlap. $strncpy$ stops after at most n chars, and $does$ not add null-terminating char.
<pre>strcat(dst, src), strncat(dst, src, n)</pre>	concatenate src onto the end of dst . strncat stops concatenating after at most n characters. <u>Always</u> adds a null-terminating character.
<pre>strspn(str, accept), strcspn(str, reject)</pre>	<pre>strspn returns the length of the initial part of str which contains only characters in accept. strcspn returns the length of the initial part of str which does not contain any characters in reject.</pre> 1

Common string.h Functions

Function	Description					
strlen(<i>str</i>)	returns the # of chars in a C string (before null-terminating character).					
<pre>strcmp(str1, str2), strncmp(str1, str2, n)</pre>	compares two strings; returns 0 if identical, <0 if str1 comes before str2 in alphabet, >0 if str1 comes after str2 in alphabet. strncmp stops comparing after at most n characters.					
strchr(<i>str</i> , <i>ch</i>) strrchr(<i>str</i> , <i>ch</i>)	character search: returns a pointer to the first occurrence of <i>ch</i> in <i>str</i> , or <i>NULL</i> if <i>ch</i> was not found in <i>str</i> . strrchr find the last occurrence.					
strstr(haystack, n Many string functions assume valid string input; i.e., ends in a null terminator. strcpy(dst, src), first occurrence of the string input; i.e., ends in a null terminator.						
strncpy(dst, src, n)	Assumes enough space in dst . Strings must not overlap. strncpy stops after at most n chars, and <u>does not</u> add null-terminating char.					
<pre>strcat(dst, src), strncat(dst, src, n)</pre>						
strspn(str, accept), strcspn(str, reject)	strspn returns the length of the initial part of str which contains <u>only</u> characters in accept . strcspn returns the length of the initial part of str which does <u>not</u> contain any characters in reject .					

Comparing Strings

We <u>cannot</u> compare C strings using comparison operators like ==, < or >. This compares addresses!

```
// e.g. str1 = 0x7f42, str2 = 0x654d
void doSomething(char *str1, char *str2) {
    if (str1 > str2) { ... // compares 0x7f42 > 0x654d!
Instead, use strcmp.
```

The string library: strcmp

```
strcmp(str1, str2): compares two strings.

    returns 0 if identical

• <0 if str1 comes before str2 in alphabet
• >0 if str1 comes after str2 in alphabet.
   int compResult = strcmp(str1, str2);
   if (compResult == 0) {
         // equal
   } else if (compResult < 0) {</pre>
         // str1 comes before str2
   } else {
         // str1 comes after str2
```

Copying Strings

We <u>cannot</u> copy C strings using =. This copies addresses!

```
// e.g. param1 = 0x7f42, param2 = 0x654d
void doSomething(char *param1, char *param2) {
    param1 = param2; // copies 0x654d. Points to same string!
    param2[0] = 'H'; // modifies the one original string!
Instead, use strcpy.
```

The string library: strcpy

strcpy(dst, src): copies the contents of **src** into the string **dst**, including the null terminator.

```
char str1[6];
strcpy(str1, "hello");
char str2[6];
strcpy(str2, str1);
str2[0] = 'c';
printf("%s", str1);
                    // hello
printf("%s", str2);
                    // cello
```

Copying Strings - strcpy

```
char str1[6];
strcpy(str1, "hello");
char str2[6];
strcpy(str2, str1);
                                          3
                                                    5
                          'h'
                                                   '\0'
                   str1
                                          3
                   str2
```

Copying Strings - strcpy

We must make sure there is enough space in the destination to hold the entire copy, including the null-terminating character.

Writing past memory bounds is called a "buffer overflow". It can allow for security vulnerabilities!

```
char str1[14];
strcpy(str1, "hello, world!");
char str2[6];
strcpy(str2, str1); // not enough space - overwrites other memory!
                                                            10
                                                                  11
                                                                       12
                                                                            13
                       '1'
                            0'
                                                 0'
             'e'
                  '1'
                                            'w'
                                                                 'd'
                                                       'r'
                                                            '|'
                                                                       '!'
                                                                           '\0'
  str1
                        3
                                  5
                                                  - other program memory -
  str2
```

```
char str1[14];
strcpy(str1, "hello, world!");
char str2[6];
strcpy(str2, str1); // not enough space - overwrites other memory!
                                                             10
                                                                  11
                                                                       12
                                                                             13
             'e'
                  '1'
                       '1'
                                             'w'
                                                  0'
                                                                  'd'
                                                       'r'
                                                             '1'
                                                                       '!'
                                                                            '\0'
  str1
                        3
                                   5
                                                  - other program memory -
  str2
```

```
char str1[14];
strcpy(str1, "hello, world!");
char str2[6];
strcpy(str2, str1); // not enough space - overwrites other memory!
                                                             10
                                                                  11
                                                                        12
                                                                             13
             'e'
                  '1'
                       '1'
                             0'
                                             'w'
                                                  0'
                                                                  'd'
                                                       'r'
                                                             '1'
                                                                       '!'
                                                                            '\0'
  str1
                        3
                             4
                                   5
                                                  - other program memory -
  str2
```

```
char str1[14];
strcpy(str1, "hello, world!");
char str2[6];
strcpy(str2, str1); // not enough space - overwrites other memory!
                                                             10
                                                                  11
                                                                        12
                                                                             13
             'e'
                  '1'
                       '1'
                                             'w'
                                                  0'
                                                                  'd'
                                                       'r'
                                                             '1'
                                                                       '!'
                                                                            '\0'
  str1
                             4
                                   5
                                                  - other program memory -
  str2
```

```
char str1[14];
strcpy(str1, "hello, world!");
char str2[6];
strcpy(str2, str1); // not enough space - overwrites other memory!
                                                             10
                                                                  11
                                                                       12
                                                                             13
             'e'
                  '1'
                       '1'
                                             'w'
                                                  0'
                                                                  'd'
                                                       'r'
                                                             '1'
                                                                       '!'
                                                                            '\0'
  str1

                        3
                             0'
                                                   'oother program Intemord -
                                             'w'
                                                                             '\0'
  str2
```

strncpy(dst, src, n): copies at most the first n bytes from **src** into the string **dst**. If there is no null-terminating character in these bytes, then **dst** will not be null terminated!

```
// copying "hello"
char str2[5];
strncpy(str2, "hello, world!", 5); // doesn't copy '\0'!
```

If there is no null-terminating character, we may not be able to tell where the end of the string is anymore. E.g. strlen may continue reading into some other memory in search of '\0'!

```
char str2[5];
strncpy(str2, "hello, world!", 5);
int length = strlen(str2);
                                                                10
                                                                      11
                                                                           12
                                                                                 13
                   '1'

```

	0	1	2	3	4	5	6	7	8	9	10	11	12	13
str1	'h'	'e'	'1'	'1'	'o'	;		;	;	;	;	;		;

```
char str1[14];
strncpy(str1, "hello there", 5);
printf("%s\n", str1);
```

	0	1	2	3	4	5	6	7	8	9	10	11	12	13
str1	'h'	'e'	'1'	'1'	'o'	;			;				;	;

```
char str1[14];
strncpy(str1, "hello there", 5);
printf("%s\n", str1);
```

_	0	1	2	3	4	5	6	7	8	9	10	11	12	13
str1	'h'	'e'	'1'	'1'	'0'			٠.	;	;		٠.	٠.	;

char str1[14];

```
strncpy(str1, "hello there", 5);
printf("%s\n", str1);

0  1  2  3  4  5  6  7  8  9  10  11  12  13
str1 'h' 'e' 'l' 'l' 'o' ? ? ? ? ? ? ? ? ? ? ? ?
```

```
hello?[?]?
```

If necessary, we can add a null-terminating character ourselves.

String Copying Exercise

What value should go in the blank at right?

- A. 4
- B. 5
- C. 6
- D. 12
- E. strlen("hello")
- F. Something else

```
char str[ ];
strcpy(str, "hello");
```

String Exercise

What is printed out by the following program?

```
int main(int argc, char *argv[]) {
      char str[9];
3
      strcpy(str, "Hi earth");
      str[2] = ' \circ ';
5
      printf("str = %s, len = %zu\n",
              str, strlen(str));
6
      return 0;
```

```
A. str = Hi, len = 8
```

B.
$$str = Hi$$
, $len = 2$

E. None/other

We <u>cannot</u> concatenate C strings using +. This adds addresses!

```
// e.g. param1 = 0x7f, param2 = 0x65
void doSomething(char *param1, char *param2) {
    printf("%s", param1 + param2); // adds 0x7f and 0x65!
```

Instead, use **strcat**.

The string library: str(n)cat

strcat(dst, src): concatenates the contents of src into the string dst.
strncat(dst, src, n): same, but concats at most n bytes from src.

```
char str1[13];  // enough space for strings + '\0'
strcpy(str1, "hello ");
strcat(str1, "world!");  // removes old '\0', adds new '\0' at end
printf("%s", str1);  // hello world!
```

Both strcat and strncat remove the old '\0' and add a new one at the end.

```
char str1[13];
strcpy(str1, "hello ");
char str2[7];
strcpy(str2, "world!");
strcat(str1, str2);
                                                 8
                                                           10
                                                                11
                                                                     12
                                      '\0'
  str1
                            'd'
                                      '\0'
  str2
```

```
char str1[13];
strcpy(str1, "hello ");
char str2[7];
strcpy(str2, "world!");
strcat(str1, str2);
                                  5
                             4
                                                 8
                                                            10
                                                                 11
                                                                      12
                  '1'
  str1
                            'd'
                                      '\0'
  str2
```

```
char str1[13];
strcpy(str1, "hello ");
char str2[7];
strcpy(str2, "world!");
strcat(str1, str2);
                                       6
                                                            10
                                                                 11
                                                                      12
                  '1'
                                            0'
  str1
                            'd'
                                      '\0'
  str2
```

```
char str1[13];
strcpy(str1, "hello ");
char str2[7];
strcpy(str2, "world!");
strcat(str1, str2);
                                                           10
                                                                11
                                                                      12
                 '1'
                                            0'
  str1
                            'd'
                                      '\0'
  str2
```

```
char str1[13];
strcpy(str1, "hello ");
char str2[7];
strcpy(str2, "world!");
strcat(str1, str2);
                                                  8
                                                            10
                                                                 11
                                                                       12
                  '1'
                                                       '1'
                                            0'
  str1
                            'd'
                                      '\0'
  str2
```

```
char str1[13];
strcpy(str1, "hello ");
char str2[7];
strcpy(str2, "world!");
strcat(str1, str2);
                                                  8
                                                            10
                                                                 11
                                                                      12
                  '1'
                                                      '1'
                                            0'
  str1
                            'd'

                                            0'
  str1
                            'd'
                                      '\0'
  str2
```

```
char str1[13];
strcpy(str1, "hello ");
char str2[7];
strcpy(str2, "world!");
strcat(str1, str2);
                                                   8
                                                                        12
                                                             10
                                                                  11
                  '1'
                                                       '1'
                                                             'd'
                                                                       '\0'
                                             0'
  str1
                             'd'
                                       '\0'
  str2
```

```
char str1[13];
strcpy(str1, "hello ");
char str2[7];
strcpy(str2, "world!");
strcat(str1, str2);
                                                  8
                                                             10
                                                                  11
                                                                       12
                  '1'
                                                       '1'
                                                            'd'
                                                                       '\0'
                                             0'
  str1
                            'd'
                                       '\0'
  str2
```

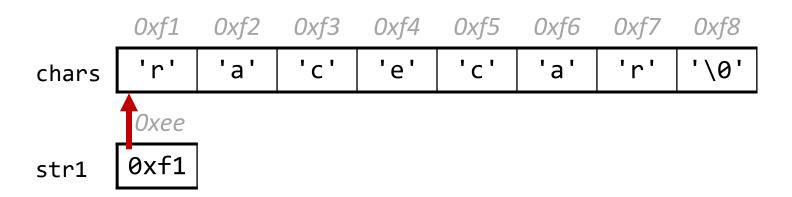

Substrings and char *

You can also create a char * variable yourself that points to an address within in an existing string.

```
char myString[3];
myString[0] = 'H';
myString[1] = 'i';
myString[2] = '\0';
char *otherStr = myString; // points to 'H'
```

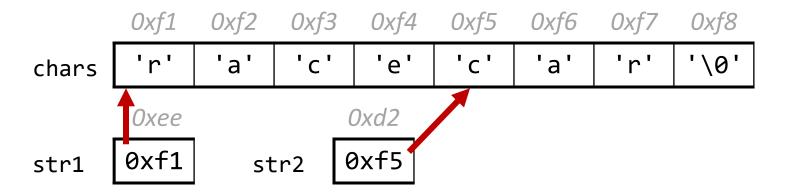

char *s (pointers to characters) *are strings*. We can use them to create substrings of larger strings.

```
// Want just "car"
char chars[8];
strcpy(chars, "racecar");
char *str1 = chars;
```

Since C strings are pointers to characters, we can adjust the pointer to omit characters at the beginning.

```
// Want just "car"
char chars[8];
strcpy(chars, "racecar");
char *str1 = chars;
char *str2 = chars + 4;
```

Since C strings are pointers to characters, we can adjust the pointer to omit characters at the beginning.

```
char chars[8];
strcpy(chars, "racecar");
char *str1 = chars;
char *str2 = chars + 4;
printf("%s\n", str1);
                                   // racecar
printf("%s\n", str2);
                                   // car
                            0xf3
                                 0xf4
                                      0xf5
                                          0xf6
                       0xf2
                                               0xf7
                                                    0xf8
                            'c'
                                 'e'
                                           'a'
                                                'r'
                                                    '\0'
            chars
                               0xd2
                  Oxee
                  0xf1
                               0xf5
            str1
                          str2
```

Since C strings are pointers to characters, we can adjust the pointer to omit characters at the beginning. **NOTE:** the pointer still refers to the same characters!

```
char chars[8];
strcpy(chars, "racecar");
char *str1 = chars;
char *str2 = chars + 4;
str2[0] = 'f';
printf("%s %s\n", chars, str1);
printf("%s\n", str2);
                              0xf3
                                    0xf4
                                         0xf5
                                              0xf6
                         0xf2
                                                   0xf7
                               'c'
                                               'a'
                                                         '\0'
             chars
                                  0xd2
                   0xf1
                                  0xf5
             str1
                            str2
```

Since C strings are pointers to characters, we can adjust the pointer to omit characters at the beginning. **NOTE:** the pointer still refers to the same characters!

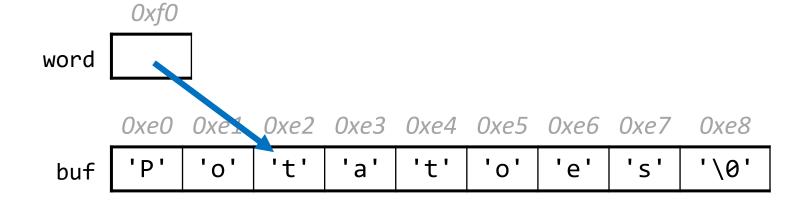

```
char chars[8];
strcpy(chars, "racecar");
char *str1 = chars;
char *str2 = chars + 4;
str2[0] = 'f';
printf("%s %s\n", chars, str1);
                                           // racefar racefar
printf("%s\n", str2);
                                             far
                                   0xf4
                                        0xf5
                                             0xf6
                        0xf2
                              0xf3
                                                  0xf7
                              'c'
                                              'a'
                                                        '\0'
             chars
                                  0xd2
                   0xf1
                                 0xf5
             str1
                           str2
```

Strings Practice

```
1 char buf[9];
2 strcpy(buf, "Potatoes");
3 printf("%s\n", buf);
4 char *word = buf + 2;
5 strncpy(word, "mat", 3);
6 printf("%s\n", buf);
```

Line 6: What is printed?

- A. matoes
- B. mattoes
- C. Pomat
- Pomatoes
- E. Something else
- F. Compile error

char * vs. char[]

- char * is an 8-byte pointer it stores an address of a character
- char[] is an array of characters it stores the actual characters in a string
- When you pass a char[] as a parameter, it is automatically passed as a char *
 (pointer to its first character)
- Stay tuned for next lecture for more!

char * vs. char[]

```
char myString[]
     vs
char *myString
```

You can create char * pointers to point to any character in an existing string and reassign them since they are just pointer variables. You **cannot** reassign an array.

To omit characters at the end, make a new string that is a partial copy of the original.

```
// Want just "race"
char str1[8];
strcpy(str1, "racecar");

char str2[5];
strncpy(str2, str1, 4);
str2[4] = '\0';
printf("%s\n", str1);  // racecar
printf("%s\n", str2);  // race
```

We can combine pointer arithmetic and copying to make any substrings we'd like.

```
// Want just "ace"
char str1[8];
strcpy(str1, "racecar");

char str2[4];
strncpy(str2, str1 + 1, 3);
str2[3] = '\0';
printf("%s\n", str1);  // racecar
printf("%s\n", str2);  // ace
```

Recap

- Characters
- Strings
- Common String Operations
 - Comparing
 - Copying
 - Concatenating
 - Substrings

Next time: more strings

Lecture 4 takeaway: C strings are null-terminated arrays of characters. We can manipulate them using string and pointer operations.

Extra Practice

Copycat exercise

Challenge: implement strcat using other string functions.

```
char src[9];
strcpy(src, "We Climb");
char dst[200];  // lots of space
strcpy(dst, "The Hill ");

How could we replace a call
to strcat with a call to strcpy
instead?
```

Copycat exercise

Challenge: implement strcat using other string functions.
